## Executive Summary

The PGCCDBS (2014) proposed a full scale herring otolith exchange for the Atlantic and Baltic Seas to take place in 2015. The current exchange was initiated in 2015 and followed a small calibration exercise where only 3 institutes participated in reading otoliths from the North Sea and Irish Sea areas. It includes samples from the North Sea, Celtic Sea, Irish Sea and VIa (North and South) areas and was completed by 13 readers from 9 institutes. The aim of this combined exchange was to assess the accuracy of the age readings i.e. the proximity of the estimated ages to the modal age which is determined by an index of average percentage error (APE), percentage agreement and relative bias values, and to assess the precision i.e. the reproducibility of age estimates between readers which is determined using the coefficients of variation (CV). In addition, growth curves were compiled based on the distance data between annotations made on the otolith images hosted on the online annotation tool, WebGR. The growth curves allow for detailed examination of where the main problems with age interpretation are. Finally, Age Error Matrices were compiled for each area; these provide a measure of accuracy of the age readings and will be provided to HAWG 2016.

For the North Sea area (based on expert readers only) the overall APE is $14.8 \%$. Bias in age estimates were found between the German and Dutch readers who are overestimating the ages in comparison to the modal age. Overall CV was 21.1 \% and overall percentage agreement 73.6\%.

For the Celtic Sea area (based on expert readers only) the overall APE is 14.2\%. Bias in age estimates were found between the German and Dutch readers who are overestimating the ages in comparison to the modal age and to a lesser extent the Northern Ireland reader who is underestimating the ages in comparison to the modal age. Overall CV was $19.6 \%$ and overall percentage agreement $75.2 \%$.

For the Irish Sea area (based on expert readers only) the overall APE is $11.6 \%$. Bias in age estimates were found between the German and Dutch readers who are overestimating the ages in comparison to the modal age and to a lesser extent the Northern Ireland reader and one reader from Norway who are underestimating the ages in comparison to the modal age. Overall CV was $16 \%$ and overall percentage agreement 77.7\%.

For the West of Scotland Sea area (based on expert readers only) the overall APE is $13.6 \%$. Bias in age estimates were found between the German and Dutch readers and to a lesser extent two readers from Norway who are overestimating the ages in comparison to the modal age. Overall CV was 18.8 \% and overall percentage agreement 69.1\%.

The combined results show that 3 of the readers (2 of which are experts) are showing significant bias in their age readings. This maybe partly due to the differences which arise in age estimates when fish are aged in terms of "rings" versus "years". The third reader is repeatedly omitting the first winter ring in the count of age. The age error matrices show that, in most cases, ages are overestimated my more than one year and this indicates that there is more than one ageing problem. The results of the growth curve analyses confirm this but annotation standardisation problems are apparent which can confound the results. Bias tests and plots give a more detailed description of reader performance.

## Introduction

The PGCCDBS (2014) proposed a full scale herring otolith exchange for the Atlantic and Baltic Seas to take place in 2015. Prior to the full scale exchange taking place a small calibration exercise was initiated by Denmark's National Institute of Aquatic Resources and AFBI Northern Ireland in 2014 to test for age reading problems, this was done in preparation for HAWG 2015 and included otolith samples from areas IVa, IVb, IVc and VIIa. The level of accuracy of the participants' age readings compared to modal age is indicated by percentage agreement (\%agreement), (a high value suggests good agreement). The level of precision i.e. the reproducibility of age estimates is indicated the coefficient of variation (CV), (a low value indicates a high level of reproducibility). The primary age readers from Denmark, Northern Ireland and Scotland participated. For both areas the \%agreement was low and the CV high: North Sea-78.8\% agreement and CV of $15.5 \%$ and Irish Sea $-86.7 \%$ agreement and CV of $7.4 \%$. In both cases the 2 experienced readers (Denmark and Scotland) had a high level of agreement but the inexperienced reader (Northern Ireland) was not in agreement. It was not possible to complete the growth curve analysis as not all readers annotated the images correctly. The aim of the current exercises is to expand on the 2014 exercise, both in terms of number of participants and areas covered (North Sea, Irish Sea, Celtic Sea and Vla West of Scotland) and to provide a more thorough analysis, including growth zone analysis and compilation of age error matrices for HAWG 2016. Preparations are underway for the Baltic Sea exchange.

## Participants

## Samples

In the early planning phase of the exchange a discussion between the stock co-ordinators lead to the decision that the exchange sets should include only autumn and winter spawning stocks to avoid confusion with stocks which have a different birth date. It was anticipated that the exchange sets would comprise of pairs of unmounted otoliths. Many of the participating institutes mount their otoliths in histokitt or resin which can cause problems when the otoliths are being digitised. Also, in many cases only single otoliths are available. Every effort was used to include pairs of unmounted otoliths in order to optimise the quality of the exchange sets made available to the readers. The exchange consisted of 4 sets of otoliths, one for each of the following areas: North Sea, Irish Sea, Celtic Sea and Vla (N and S), with 50 images per area.

Otoliths from the North Sea (IVa and IVb) were provided by DTU Aqua (Table 2). These had not been mounted in resin or histokitt.

Table 2. Sample overview for the North Sea

| North Sea | $\begin{aligned} & \text { Jan'13 } \\ & \text { Q. } 1 \end{aligned}$ | $\begin{aligned} & \text { Feb '13 } \\ & \text { Q. } 1 \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { Jun '14 } \\ & \text { Q. } 2 \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { Jul'13 } \\ & \text { Q. } 3 \end{aligned}$ | $\begin{aligned} & \text { Aug '13 } \\ & \text { Q. } 3 \end{aligned}$ | $\begin{aligned} & \text { Aug '14 } \\ & \text { Q. } 3 \end{aligned}$ | $\begin{aligned} & \text { Sep'13 } \\ & \text { Q. } 3 \end{aligned}$ | $\begin{aligned} & \text { Oct '13 } \\ & \text { Q. } 4 \end{aligned}$ | $\begin{aligned} & \text { Nov '13 } \\ & \text { Q. } 4 \end{aligned}$ | $\begin{aligned} & \text { Dec '13 } \\ & \text { Q. } 4 \end{aligned}$ | Total |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| IVa | 3 |  | 7 |  |  | 4 |  | 7 | 2 | 4 | 27 |
| IVb | 4 | 3 |  | 2 | 11 |  | 1 |  |  | 2 | 23 |
| Total | 7 | 3 | 7 | 2 | 11 | 4 | 1 | 7 | 2 | 6 | 50 |

Otoliths from the Celtic Sea (VIIg, VIIj and VIIaS) were provided by the Marine Institute Ireland (Table 3). A large number of samples were originally chosen for the exchange. As many of these were mounted in resin on black slides they were not suitable for digitisation. All of the samples were visually inspected and the best quality otoliths were used for the exchange.

Table 3. Sample overview for the Celtic Sea

| Celtic Sea | Sep'11 <br> Q.3 | Oct '11 <br> Q.4 | Oct '13 <br> Q.4 | Nov '11 <br> Q.4 | Nov'14 <br> Q.4 | Dec'11 <br> Q.4 | Dec'13 <br> Q.4 | Total |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| VIIaS |  |  |  | 1 |  | 5 | 8 | 14 |
| VIIg | 10 | 5 | 2 |  | 10 |  |  | $\mathbf{2 7}$ |
| VIIj |  | 9 |  |  |  |  |  | $\mathbf{9}$ |
| Total | $\mathbf{1 0}$ | $\mathbf{1 4}$ | $\mathbf{2}$ | $\mathbf{1}$ | $\mathbf{1 0}$ | $\mathbf{5}$ | $\mathbf{8}$ | $\mathbf{5 0}$ |

Otoliths from the Irish Sea (VIIa) were provided by AFBI Northern Ireland (Table 4). All of the otoliths had been mounted in resin on black slides. All of the samples were visually inspected and the best quality otoliths were used for the exchange.

Table 4. Sample overview for the Irish Sea

| Irish | Mar'11 | Sep '06 | Sep '11 | Oct '10 | Total |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Sea | Q.1 | Q.3 | Q.3 | Q.4 |  |

| Total | $\mathbf{1 2}$ | $\mathbf{9}$ | $\mathbf{1 1}$ | $\mathbf{1 8}$ | $\mathbf{5 0}$ |

Otoliths from the West of Scotland (VlaN and VIaS) were provided by MARLAB Scotland (Table 5). These had not been mounted in resin or histokitt.

Table 5. Sample overview for VIa ( N and S )

| VIa (N and S) | Feb '15 | Mar'15 | Aug'14 | Sep'14 | Nov'14 | Total |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  | Q.1 | Q.1 | Q.3 | Q.3 | Q.4 |  |
| VlaN | 6 | 1 | 6 | 5 | 7 | $\mathbf{2 5}$ |
| VlaS | 16 |  |  |  | 9 | $\mathbf{2 5}$ |
| Total | $\mathbf{2 2}$ | $\mathbf{1}$ | $\mathbf{6}$ | $\mathbf{5}$ | $\mathbf{1 6}$ | $\mathbf{5 0}$ |

## Methods

All otolith were sent to DTU Aqua to ensure that a standard set up and magnification was used for all images. Images of whole otoliths immersed in alcohol were taken on a black background under reflected light using a Leica MZ6 stereo microscope (magnification x2), Leica DFC320 camera and the corresponding Leica Application Software V.4.5. A total of 200 otoliths ( 50 per area) were digitised and made available on WebGR for annotation.

Prior to the exercise a Skype meeting was held where all readers and national age reader co-ordinators were invited to attend. A demonstration of WebGR plus a demonstration of how the readers were required to annotate the images was given. Readers were also provided with written instructions and an image example of which axis to annotate. They were asked to annotate the nucleus and the start of each translucent zone and give a final estimation of age. The exercises were run as blind tests where the readers could not see the annotations of the other readers.

Four separate calibration exercises were made available on WebGR: North Sea Herring, Irish Sea Herring, Celtic Sea Herring and VIa Herring. All readers will be required to read the otoliths from all areas. Readers were provided with information on the capture date, area and total length (TL).

## Analysis

Each of the 4 calibration exercises were analysed separately.

## Age data:

An R script was developed which follows the traditional analyses of agreement between readers as used in the Guus Eltink spreadsheet (Eltink, A.T.G.W. 2000):

- average \% Agreement (nmodal age/ntotal*100)
- coefficient of variation (CV) (Standard deviation/average*100)
- bias tests and plots

In addition an index of average percentage error (APE) was calculated based on the method outlined by Beamish \& Fournier (1981). This method is not independent of fish age and thus provides a better estimate of precision. As the calculations of both CV and APE poses problems if the mean age is close to 0 , all observations for which modal age was 0 were omitted from the CV and APE calculations. Inter-reader bias was tested using the Friedman rank sum test followed by a post-hoc pairwise Wilcoxon test for multiple comparisons.
Age error matrices were produced following procedures outlined by WKSABCAL (2014) where the matrix shows the proportion of each modal age mis-aged as other ages. The sum of each row is 1 , equal to $100 \%$. For each area all readers were included.

## Growth data:

WebGR provides a measure of distance between the annotations made by the readers and thus provides a measure of growth increment width. The "alldistances" dataset from WebGR was used to establish growth curves for each fish and for each reader. For each set of annotations belonging to a single fish and reader, the distance between two consecutive annotations was added to the sum of the previous distances and the distances were cumulated from centre point to the outermost annotated winter ring. These growth curves were analysed using Linear Mixed Effects Models (LMEM).

For all 4 exchanges the model that best fits the data is a model with log (winter ring) and reader as fixed effects and individual images as random effects. The results show significant differences ( $p<0.05$ ) in the intercept of the LMEM indicating there are differences in the interpretation of the first winter ring and significant differences ( $p<0.05$ ) in the slope of the LMEM indicating there are differences in the interpretation of the following winter rings. A post-hoc Tukey Contrasts test for multiple pairwise comparisons followed to identify inter reader differences.

While the age data provides information on whether the age readers agree in age estimates, the growth data can identify specifically where the problems are, i.e. differences in intercept only are attributable to problems with the first winter ring, while differences in slope indicate a general inconsistency in structures used for age estimation.

## Results

## North Sea Exchange

## Age data:

When all of the age readers are included the overall percentage agreement is $70.3 \%$ with a CV of $24.2 \%$. Problems are already apparent at fish age 0 where the $\%$ agreement is only $77 \%$ due to three of the readers (NOR1, NLD1 and DEU1) assigning an age of 1 to these fish. NLD1 and DEU1 appear to add an extra age without making an annotation whereas NOR1 marks an extra ring at the edge. In general, the level of agreement decreases as fish age increases (Table 2a). Fish IV_35 (Fig 1a) has the highest level of agreement
at $92 \%$ with only DEU1 reading age 5 when the modal age is age 4 . The lowest level of agreement is $38 \%$ where ages ranging from 8 to 13 are assigned to a fish with modal age 9. The overall CV for modal age 1 is very high at $45 \%$, as only 6 of the 13 readers have a CV of 0 . CV decreases to the lowest level of $9.3 \%$ for modal age 5 before increasing again. When only the "expert" readers are included in these calculations the overall \% agreement increases slightly to $73.6 \%$ and the CV decreases to $21.1 \%$. The overall index of average percentage error (APE) is $17.2 \%$ and when calculated based on only the "expert" readers this improves to $14.8 \%$.

Figure 1a. Herr_IV_35. Modal age 4, capture date 04/09/2013, \% agreement 92\% and CV 7\%
Table 1a shows the age composition based on the estimated ages for all readers. Tables 2a, 3a and 4a show the \% Agreement, CV and relative bias based on modal age for all readers.

Table 1a. Age composition based on all readers in the North Sea exchange

Significant bias in age estimates was found between readers (Friedman rank sum test, p < 0.05 and Wilcoxon paired test, $p<0.05$ ). Table 5 a shows the results of the Inter reader and reader against modal age bias tests and indicates that there is bias between readers NLD1, DEU1 and NOR1 and all of the other readers and also with modal age. These results are confirmed by the high positive values of relative bias for these readers (Table 4a), indicating that these readers are generally over estimating the ages in comparison
to the modal age. The age bias plots in Annex 1 confirm these results. The general trend seen in the relative bias values (Table 4a) is for the ages to be overestimated as opposed to underestimated in comparison to modal age, which is also apparent in the age error matrix in Table 6a.

Table 5a. Inter reader bias test for all readers in the North Sea exchange. "-" = no sign of bias ( $p>0.05$ ); "*" = possibility of bias ( $0.01<\mathrm{p}<0.05$ ) and "**" $=$ certainty of bias ( $\mathrm{p}<0.01$ ).

## Growth data:

Figure 2a shows the combined growth curves for all fish and all readers in the North Sea exchange. FRA1 omitted to mark the centre point on every image and therefor his average growth curve falls below all of the others. He was omitted from the analysis. The Linear Mixed Effects Model analysis showed a significant reader effect on both the intercept and slope of the LMEM (LMEM, p<0.05) meaning that there are differences between readers. The post-hoc analysis revealed that GBR1, NDL1, NOR1 and NOR4 stand out from the other readers (just significant) and thus what they are interpreting to be the winter rings differ slightly from the rest of the group. The overlap between GBR1 winter ring 1 and winter ring 2 of the other readers indicates that what he interprets as the first winter ring is in fact the second winter ring. Despite this he still attains a higher overall age.

Figure 2a. Plot of average distance to the centre for winter rings 1-10 for all readers in the North Sea exchange. The boxes represent the mean, upper and lower box boundaries of the interquartile range, whiskers represent the minimum and maximum values and the dots represent the outliers.

## Celtic Sea Exchange

## Age data:

When all of the age readers are included the overall percentage agreement is $73.8 \%$ with a CV of $19.8 \%$. For ages $0-4$ the average agreement is above $75 \%$ with a general decrease in agreement with an increase in age. The CV for modal age 1 is high at $45.4 \%$. NLD1 is overestimating the age by 2 years in most cases and DEU1 overestimating by 1 year in most cases (Figure 1b). This trend continues with the older fish and is confirmed by the relative bias values (Table 4.b) which also shows GBR1 and IRL1 to have a strong negative bias values indicating underestimation of ages in comparison to modal age. CV decreases to a low of 9.1\% at modal age 7 but increases slightly again. When only the "expert" readers are included the $\%$ agreement increases slightly to $75.2 \%$ while the CV improves slightly to $19.6 \%$. The overall index of average percentage error (APE) is $13.5 \%$ which when calculated on only the "expert" readers increases to $14.2 \%$.

Figure 1b. Herr_VII_39, capture date 02/12/2013, modal age 6, \% agreement 77\% and CV 11\%. Readers GBR1 (blue), NOR5 (black), DEU1 (red) and NLD1 (green) assigning ages 5, 6, 7 and 8 years respectively.

Table 1 b shows the age composition based on the estimated ages for all readers. Tables $2 b, 3 b$ and $4 b$ show the \% Agreement, CV and relative bias based on modal age for all readers.

Significant bias in age estimates was found between readers (Friedman rank sum test, p<0.05 and Wilcoxon paired test, $\mathrm{p}<0.05$ ). Table 5 b shows the results of the Inter reader and reader against modal age bias tests and indicates that there is a certainty of bias between NLD1 and DEU1 against the other readers
and modal age. There is also a possibility of bias between GBR1, FRA1 and NOR1 and some of the readers but not against modal age. IRL1 shows some possible bias with some of the readers and with modal age. These results are confirmed by the relative bias values in Table 4.b and the age bias plots in Annex 2. The general trend seen in the relative bias values (Table 4b) is for the ages to be overestimated as opposed to underestimated in comparison to modal age, which is also apparent in the age error matrix in Table 6b.

Table 5b. Inter reader bias test for all readers in the Celtic Sea exchange where "-" = no sign of bias ( $\mathrm{p}>0.05$ ); "*" $=$ possibility of bias ( $0.01<\mathrm{p}<0.05$ ) and "**" $=$ certainty of bias ( $\mathrm{p}<0.01$ ).

## Growth data:

Figure $2 b$ shows the combined growth curves for all fish and all readers in the Celtic Sea exchange. FRA1 omitted to mark the centre point on every image and therefor his average growth curve falls below all of the others. He was omitted from the analysis. The Linear Mixed Effects Model analysis showed a significant reader effect on both the intercept and slope of the LMEM (LMEM, p<0.05) meaning that there are differences between readers. The same results are seen as with the North Sea exchange where the posthoc analysis revealed that GBR1, NDL1, NOR1 and NOR4 stand out from the other readers (just significant) and thus what they are interpreting to be the winter rings differ slightly from the rest of the group. This is most obvious for GBR1 as what he interprets to be winter ring 1 is in fact winter ring 2 (Figure 1b).

## Irish Sea Exchange

## Age data:

When all of the age readers are included the overall percentage agreement is $76.9 \%$ with a CV of $16.6 \%$. For modal ages 1 and 2 the $\%$ agreement is high at $84 \%$ and $80 \%$ respectively but decreases with an increase in fish age. The \% agreement would be higher at these low ages if NLD1 and DEU1 were not overestimating the ages (both have $0 \%$ agreement at ages 1,2 and 3 ). This trend continues with the older fish and is confirmed by the positive relative bias values in Table 4c which also show GBR1 to have a strong overall negative bias. At modal ages 1 and 2 CV is high at 32.7 and $20 \%$ respectively. This gradually decreases to a low of $10.1 \%$ at modal age 6 before increasing again. When only the "expert" readers are included the \% agreement only improves slightly to $77.7 \%$ while the CV decreases to $16 \%$. The overall index of average percentage error (APE) is $11 \%$ and when calculated based on only the "expert" readers is $11.6 \%$.

Table 1 c shows the age composition based on the estimated ages for all readers. Tables $2 \mathrm{c}, 3 \mathrm{c}$ and 4 c show the \% Agreement, CV and relative bias based on modal age for all readers.

Significant bias in age estimates was found between readers (Friedman rank sum test, p<0.05 and Wilcoxon paired test, $\mathrm{p}<0.05$ ). Table 5 c shows the results of the Inter reader and reader against modal age bias tests and indicates that there is a certainty of bias between NLD1 and DEU1 against the other readers and modal age. NOR2 also shows certainty of bias against modal age and a possibility of bias against some
of the other readers. There is a possibility of bias between GBR1 and IRL1 and some of the other readers and also modal age. These results are confirmed by the relative bias values in Table 4c and the age bias plots in Annex 3. The general trend seen in the relative bias values (Table 4c) is for the ages to be overestimated as opposed to underestimated in comparison to modal age, which is also apparent in the age error matrix in Table 6c.

Table 5c. Inter reader bias test for all readers in the Irish Sea exchange. "-" = no sign of bias ( $p>0.05$ ); "*" $=$ possibility of bias ( $0.01<\mathrm{p}<0.05$ ) and "**" $=$ certainty of bias ( $\mathrm{p}<0.01$ ).

## Growth data:

Figure 3a shows the combined growth curves for all fish and all readers in the Irish Sea exchange.
FRA1 omitted to mark the centre point on every image and therefor his average growth curve falls below all of the others. He was omitted from the analysis. The Linear Mixed Effects Model analysis showed a significant reader effect on both the intercept and slope of the LMEM (LMEM, $p<0.05$ ) meaning that there are differences between readers. The results are more varied this time and the post-hoc analysis revealed more significant differences between the readers. NOR2, NOR3, NOR4 and NOR5 annotations are similar while the rest of the group appear to be annotating the images somewhat differently.

## VIa (N and S) Exchange

## Age data:

When all of the age readers are included the overall percentage agreement is $66.8 \%$ with a CV of $20 \%$. For modal ages 0-3 the \% agreement is above $70 \%$ with a general decrease seen with an increase in fish age. Figure 4a shows fish VIa_37, modal age 1, \% agreement of $69 \%$ and CV of $58 \%$. For modal age 1 the average CV is very high at $48.5 \%$, this is partly due to general mis interpretation of the structures combined with a routine overestimation of these young fish by NLD1 and DEU1. This trend continues with the older fish and is shown by the strong positive bias values (Table 4d) for these 2 readers. The CV decreases to a low of $11.4 \%$ at age 5 before increasing slightly again. When only the "expert" readers are included the \% agreement increases to $69.1 \%$ and the CV improves to $18.8 \%$. The overall index of average percentage error (APE) is $13.8 \%$ and when calculated based only on the "expert" readers is $13.6 \%$.

Figure 4a. Herr Vla_37, capture date 25/02/15, 69\% agreement, CV 58\% and modal age 1. Readers NOR1 (yellow), GBR2 (blue) and NLD1 (green) assigning ages of 0,1 and 2 respectively.

Table 1d shows the age composition based on the estimated ages for all readers. Tables 2d, 3d and 4d show the \% Agreement, CV and relative bias based on modal age for all readers.

Significant bias in age estimates was found between readers (Friedman rank sum test, p < 0.05 and Wilcoxon paired test, $\mathrm{p}<0.05$ ). Table 5d shows the results of the Inter reader and reader against modal age bias tests and indicates that there is a certainty of bias between NLD1 and DEU1 against the other readers and modal age. NOR1 and NOR4 show a possibility of bias against some of the other readers. These results are confirmed by the relative bias values in Table 4d and the age bias plots in Annex 4. The general trend seen in the relative bias values (Table 4d) is for the ages to be overestimated as opposed to underestimated in comparison to modal age, which is also apparent in the age error matrix in Table 6d.

Table 5d. Inter reader bias test for all readers in the VIa ( N and S ) exchange. "-" = no sign of bias ( $\mathrm{p}>0.05$ ); "*" $=$ possibility of bias $(0.01<p<0.05)$ and $" * * "=$ certainty of bias ( $p<0.01$ ).

## Growth data:

Figure 4b shows the combined growth curves for all fish and all readers in the VIa ( N and S) exchange. FRA1 omitted to mark the centre point on every image and therefor his average growth curve falls below all of the others. He was omitted from the analysis. The Linear Mixed Effects Model analysis showed a significant reader effect on both the intercept and slope of the LMEM (LMEM, p<0.05) meaning that there are differences between readers. GBR1 and GBR2 stand out from the others readers (significant). GBR1 usually omits to mark the first winter ring and on some images is marking along the wrong axis. GBR2 has problems with the older fish. NOR1 also appears to be annotating slightly different in comparison to the other readers.

## Conclusion

This full scale exchange covers 4 separate stocks (North Sea, Celtic Sea, Irish Sea and VIa (North and South) and was completed by 13 readers (10 of which are experts) from 9 institutes. It is not surprising that in comparison to the 2014 calibration exercise the percentage agreement for both the North Sea and Celtic Sea's has decreased given that, firstly, the number of participants has increased from 3 to 10 and secondly, not all readers are experienced in reading otoliths from all areas.

The index of average percentage error (APE) ranges from $11.6 \%$ to $14.8 \%$ and the coefficient of variation (CV) from $16 \%$ to $21.1 \%$ and similar problems are apparent for all stocks. For each stock there is a general trend where the overall relative bias values are positive meaning that the readers overestimate the ages in comparison to the modal age. This can also be seen in the age error matrices. This overall positive bias is due mostly to readers NLD1 and DEU1 who are repeatedly estimating 1 and sometimes 2 years over the modal age. For herring stocks, there can be confusion as to whether a fish is aged in terms of "rings" or "years". For autumn spawning herring stocks a difference of one year becomes apparent between the count of "rings" and "years". Readers were asked to provide the age in terms of "years". Providing an age based on a count of "rings" would explain the addition of one extra year to the age, additional years added to the age are then due to misinterpretation of the otoliths structure. The definition of age for these fish should be standardised to avoid further confusion.

In the 2014 calibration exercise the less experienced reader from Northern Ireland (GBR1) had a tendency to underestimate the age as the first winter ring was often not counted. This problem is still apparent and is most obvious by the comparison of the growth curves. The relative bias values confirm this underestimation for both the Celtic Sea and Irish Sea exercises. Interpretation of the subsequent winter rings can also lead to overestimation in some examples, more noticeably the younger fish.

The only other reader who clearly stands out from the group is NOR1, who is a trainee. In general she is overestimating the ages, partly due to misinterpretation of the edge.

For all areas the level of accuracy and precision improves dramatically when the problematic and inexperienced readers are excluded from the calculations. This improvement is slightly less for VIa ( $\mathrm{N} \& \mathrm{~S}$ ). Thus, the compilation of agreed age collections of otoliths should be possible.

The growth curve analyses showed that both the first winter ring and the additional winter rings are interpreted differently by the group and clearly shows the issues associated with the misidentification of the first winter ring for GBR1. The issues associated with incorrectly annotating the images are also apparent as FRA1 omitted to mark the nucleus each time. Some of the other readers did not follow the instructions correctly and different axes were annotated on some occasions. This could lead to a significant difference revealed by the post-hoc analyses. The standardisation of annotation procedures is difficult and it is clear from the images that what the readers interpret to be the nucleus is not exact, nor do all readers interpret the beginning of each winter ring to be in the same place. As the fish age increases the distance between winter rings decreases and annotating the winter rings becomes more difficult, thus the overlap in the distance from centre to winter ring is more apparent for the older fish (from age 6 and over). Written
instructions and a live demonstration using WebGR were provided for the readers but standardisation of annotation procedures is still difficult and may confound the growth analyses results.

Given that for some of the stocks there are just 1 or 2 readers providing age estimates for assessment it did not make sense to compile age error matrices for all stocks. A North Sea matrix will be compiled based only on those readers providing age data for assessment and provided to HAWG 2016.

| RECOMMENDATION | ADRESSED TO |
| :--- | :---: |
| 1. Compilation of a reference collection of agreed age fish | Age reading labs and WGBIOP |
| 2. Standardisation of whether it is the count of "year" or "rings" which are used to define <br> fish age for age reading exercises. | WGBIOP |
| 3. Standardiation of procedures for annotation of images used in exchanges. | WGBIOP |
