No. 14 K

Second Report of The Bluefin Tuna Working Group

by

J. Hamre & K. Tiews

Digitalization sponsored  
by Thünen-Institut

## 1. Introduction

At the invitation of the Norwegian Institute of Marine Research, the 2nd meeting of the Bluefin Tuna Working Group was held in Bergen from the 2nd to the 5th of April, 1963. Prior to the meeting the member countries of the Scombriform Fish Committee were requested to submit all available bluefin tuna catch statistics. Data have been submitted by Denmark, France, Germany, Norway and Portugal.

Apart from the member countries of ICES, Dr. H. Aloncle of the Institut des Pêches Maritimes du Maroc was contacted and has been so kind to submit data on the Moroccan bluefin tuna catches for the season 1962. In addition to the compilation of the 1962-materials, the Working Group has also compiled statistics of the German and Norwegian tuna catches made during the years 1956-59, so that now a complete picture of the catch composition of the German and Norwegian tuna catches is available as from 1956.

## 2. Methodology

In the 1st report of the Working Group it has been proposed to compile the catch composition data of the various countries uniformly on a weekly basis, since the single runs of tuna are usually so short that any larger time interval can hardly reveal the expected interdependence existing between the different distribution areas. Further to this the following definitions were adopted during our 2nd meeting:-

Time interval: all weeks, extending from Sunday to Saturday, should be continuously numbered throughout any one year, whereby the week, in which the 1st of January falls, should be counted as week No.1.

In order to avoid misunderstandings, it is desirable when tabulating materials, to add to the week number also the respective dates. The opportunity is taken here to give the following corrections for misprints made in our 1st report as to the dating of weeks:

Page 2, under 4, 1st paragr., line 10 - instead of the "34th week (20th to 26th August)" read "34th week (14th to 20th August)" and in the same paragr., last line - instead of "42nd week (17th to 23rd October 1960)" read "42nd week (9th to 15th October 1960)".

Size measurement and its grouping: in the 1st report of the Working Group it has been said that the size composition of the catches should be given either in length or in weight. However, if only one kind of data (either length or weight) can be collected, a key for the transformation from one type of data into the other should be given. Weight data should refer always to ungutted fish.

In the case of the Norwegian and German tuna catches, it has been found to be practical to group the data in weight units, which are between 5 and 10 kgs. The grouping of data does not completely correspond, since in both countries the original data refer to gutted fish, which have been gutted in different ways ( $w_N = 1,285 \cdot w_N^!$ ;  $w_G = 1,026 w_G^!$ ). As a general rule the weight units should not be greater than 5% of the average weight of the fish under study.

The length measurements should be compiled in groups not exceeding a range of 5 cm. When length measurements are taken, fork length should be measured. It has been found practical to make such measurements by means of a calliper.

### 3. Data Representation

#### 3.1 1962 catches

##### 3.1.1 Morocco

The Moroccan data refer to catches from madragues located in the vicinity of Larache during the period from the 5th of May to the 6th of June, 1962. The data give the total number and weight of fish caught for every week and permit consequently to calculate the weekly average weight of tuna (Table 1, page 5). Unfortunately, data on the more detailed catch composition are lacking. However, Dr. Aloncle, who was so kind to submit the data, is going to organize respective work for the coming tuna catch season, as he has informed the Working Group.

##### 3.1.2 Portugal

The bluefin tuna catches made in the madragues located at the south coast of Portugal are given in Table 2 (page 5).

Dr. Vilela reports that the tuna fishing along the west coast was very scarce and irregular in 1962. The only catches known to him were 150-200 small tuna of a mean weight of around 5 kg.

##### 3.1.3 France

The French landings of bluefin tuna made in Saint-Jean-de-Luz are given in Table 3 (page 6). The materials could be grouped in two size categories only, i.e., tuna below 30 kg and tuna between 30 and 70 kg. It is hoped, however, as Dr. Letacconnoux reported to the Working Group, to improve the data with regard to the recognition of the size composition of the catches in the coming catch season. It must be mentioned that the French materials refer to weeks extending from Friday to Thursday.

##### 3.1.4 Norway and Germany

Following the example of the previous compilations for 1960 and 1961, the compositions of the Norwegian and German tuna catches are given according to the three major fishing areas, i.e.,

1. North Norwegian coast (N of 63°N)
2. South Norwegian coast (S of 62°N)
3. North Sea.

In the area between the areas 1 and 2, which is being considered as a transition area (comp. Hamre, 1961), the 1962 catch was only 17 fish. Table 4 (page 6) gives the weekly length composition of the German tuna catches and Tables 5-7 (pages 7,8,9) the weekly size compositions by weight frequencies for the German and Norwegian tuna catches.

##### 3.1.5 Denmark

The Danish report gives weekly catches of bluefin tuna, which were for the first time made exclusively in the Kattegat, Skagerak, Sound and Belt Sea by the Danish fishermen. In former years catches were also made in the North Sea, and in most of the years even the larger part of the Danish tuna catch was made there, i.e., on more or less the same fishing grounds as those being used by the German fishermen. Mr. Bagge, who submitted the information, was able to give the weight of weekly landings, referring to the weight of gutted fish with head but without gills (Table 9 - page 10). No regression formula for calculating the total weight was given. Although the number of fish caught is not available, the data permit to conclude from 29 fish the individual weight (Table 8 - page 10). Nearly 90% of the Danish catches were landed at Skagen, and the largest part of these were made east of Laesø Island in the Kattegat.

#### 3.2 1956-59 catches

Apart from the 1962 materials discussed under 3.1, it was also possible to obtain data on the composition of Norwegian and German tuna catches for the years back from 1956-59, and these have been compiled in Tables 10-21 (pages 11-23).

#### 4. Comparison of Catch Composition and Discussion

##### 4.1 1962-season

As has been concluded already for 1960 and 1961 in the 1st Report of the Working Group, there were also in 1962 two major runs of tuna to the Norwegian coast, from which one, consisting of larger fish, was found from the 30th to the 37th week at the north coast of Norway, and the other from the 29th to the 41st week, i.e., during the entire fishing season, on the west coast south of 62°N. On the north Norwegian coast the largest weekly catch (3,814 tuna) was made during the 32nd week. South of 62°N, catches were best even earlier, i.e., during the 31st week, when 6,591 tuna were taken (Figure 1, page 24). If compared with the two former years under observation, the main fishing season on the southern run of tuna was earlier in 1962. This had to be expected, since they were fish of the same year-classes as in the two previous years and since it is a general experience that the older the fish, the earlier its arrival.

The fish, which was caught by the German fishermen in 1962 in the middle part of the North Sea, corresponded in its size composition again with that caught by the Norwegian fishermen on the north Norwegian coast. It had its peak of weight frequency distribution at about 260-270 kg, while the north Norwegian fish had its peak at about 250-260 kg. The small weight difference, which has been found, is very likely because the German fish was taken later in the year. This fish, which completely left the north Norwegian waters during the 37th week, was landed for the first time during the 36th week by the German fishermen. They had their main fishing season during the 39th week, i.e., 7 weeks later than the north Norwegian fishermen. In the case of the German catches, the catch composition data refer to landings, while the actual fishing time was on an average about 5-7 days earlier, as the German fishing cruises do normally extend over periods from 10-14 days.

As can be concluded from the Danish data, there was an unusual good tuna fishing in the Kattegat area, east of Laesø Island, where the tuna, according to Mr. Bagge, was found near strong herring concentrations. The peak of the catch was reached during the 41st and 42nd week, practically after the Norwegian and German fishing seasons had terminated. The fishing season there extended even until the beginning of November (4th-11th November = 45th week), and the last tuna was caught during the 51st week extending from the 16th to the 22nd of December. Neither the Norwegian nor the German fishermen have ever caught tuna at such a late date.

Although the size composition of catches were not studied by the Danish colleague, the few data available at present permit to conclude that the fish, caught in the Kattegat, was of a similar size composition as that of the Norwegian and German catches. In this connection it may be recalled that, in 1959 a tuna tagged on the west Norwegian coast was recaptured in the Kattegat near Anholt Island three weeks after tagging (Hamre, 1961).

The data available on the average weight of the tuna caught in the Moroccan madragues do unfortunately not reflect the catch composition which could be compared with the Norwegian and German data, as the madrague catches do consist of a great variety of age-groups. Therefore, it can be stated here only that the peak of the Moroccan catches was in the 22nd week and consequently 9-10 weeks earlier than in the Norwegian tuna fishery. The mean weight of the ungutted fish, which amounted to 181.5 kg, was much lower than that calculated for the Norwegian and German tuna catches.

Also the Portuguese data cannot easily be compared with the Norwegian and German data. In this case the peak of catches was reached during the 21st week, i.e., at about the same time as in Morocco. A second peak occurred during the 31st week, which corresponds with the peak of the Norwegian catches.

The French data refer to age-groups, which were not contained in the catches made in the North Sea area and its approaches. Dr. Letaconnoux reports it to be worthwhile to mention that the French catches of older fish, i.e., between 30 and 70 kg, were considerably larger than during the years 1960 and 1961. This may indicate that a stronger recruit year-class might occur in the near future on the Norwegian coast. This is in so far of special importance for the future development of northern tuna fisheries, as since 1958 recruit year-classes are lacking.

#### 4.2 1956-59 catches

The comparison of the Norwegian and German 1956-59 tuna catches principally confirms the conclusions drawn from the 1960-62 materials (Figure 2-5, pages 25-28). The summarizing Figure 6 (page 29) shows that during the years 1956, 1957, 1959, 1960, 1961, and 1962 the north Norwegian tuna catch widely corresponds in its size composition with the German tuna catch, but does much less with the west Norwegian catch. If the average weight of tuna of the German catch is a little greater, this is due to the fact that the fish was taken several weeks later and that the fish consequently has had a respectively longer stay on the feeding grounds.

A different picture, which cannot easily be explained, was obtained in 1958, when the average size of fish of the north Norwegian catch was a little higher than that of the German catch. It is possible that the tuna, which were met in the middle parts of the North Sea, was a mixture of both the north and west Norwegian tuna runs.

#### 5. Conclusions and Recommendations

The comparison of the weekly composition of tuna catches made in different areas permits to recognize the interdependence existing between the tuna occurrences in these areas. It could be shown again by means of the newly compiled materials that the tuna occurring on the north Norwegian coast are closely related to those being caught few weeks later in the middle part of the North Sea. Due to lack of suitable materials it was not possible to investigate the relationship which is expected to exist between the tuna on the northern and on the southern European fishing grounds. The close co-operation of all countries participating in this fishery is indispensable for such an analysis. In view of the recent tagging results, which indicate a trans-atlantic relationship of the bluefin tuna stocks of both sides of the Atlantic Ocean, the co-operation with the U.S.A. bluefin tuna research seems to be highly desirable.

In the previous report it was strongly recommended to immediately initiate in the ICES area collection of weekly catch composition data, and the desirability for a close co-operation with the member countries of the General Fisheries Council for the Mediterranean (GFCM) was stressed.

Further to this it is recommended that the reports of the ICES Tuna Working Group should be made available also to all institutions which deal with bluefin tuna research in the U.S.A., in order to seek also their close co-operation in this work.
