Soviet Investigations of Saithe (Pollachius virens) in the North Sea in 1966 - 1970

by

I. P. Golubjatnikova<sup>x)</sup>

Summary

Data on the size composition of saithe were collected by AtlantNIRO vessels in 1965 to 1970, the material on age composition was collected in 1966 to 1970.

The growth rate of males and females of saithe in the North Sea proved to be similar.

The growth rate of saithe from Shetland shallow waters was somewhat higher than from the southern part of the Norwegian Deep.

Catches in 1966 to 1968 were dominated by the strong 1962 year class and partly by the moderately strong year class of 1963. In the following two years (1969 - 1970) the 1966 and 1967 year classes predominated in the catches.

The bulk of the catches consisted of saithe 39 to 70 cm in length, at the age of 3 - 6 and even 7 years.

-----

Soviet fishery for gadoids in the North Sea exists since 1966. Among the gadoids, saithe was the most important commercial fish for the Soviet fishery after haddock. Catches of saithe from the North Sea are shown in Table 1. As is seen from the Table, a considerable increase in the yield of saithe occurred in the North Sea in recent years. This was the cause for the more thorough studies of this species.

An attempt was made to determine growth rate and age and size composition of the saithe in the North Sea. The material included age samples and mass length measurements made in commercial trawl catches and catches from trawls with a fine-meshed cover (8-10 mm). Age was determined by means of otoliths. Age composition was obtained by extrapolation of the results

of the mass measurements. The investigations of growth rate are based on direct observations.

The data on male and female growth rate are given in Table 2 for the period 1968 to 1970. The comparison of these data shows a similar growth of males and females. Therefore, later on the growth rate of saithe from various areas were compared without sex differentiations.

In the Shetland shallow waters the growth rate of saithe was somewhat higher than in the southern part of the Norwegian Deep (Table 3). This higher growth rate in the area of the Shetland shallow waters can be explained by mixing the different stocks. As was noted earlier (Saemundsson, 1929; Schmidt, 1955) saithe inhabiting Iceland waters is characterised by a higher growth rate than saithe from Norwegian waters. Bertelsen (1942) discovered that saithe from the Faroe waters are characterised by a growth rate which is intermediate between the growth rates of saithe of Icelandic and Norwegian origin. At the same time (Anon. 1965) it was found that saithe migrate from the Faroe and Shetland Island areas towards Iceland, into the North Sea and to the coast of Norway.

The age composition of saithe from the North Sea is presented in Table 4, while the size composition is given in Table 5.

Table 4 shows that in 1966 to 1968 catches were dominated by specimens of the strong 1962 year class and partly of the moderately strong year class of 1963. These data coincide with those of Draganik (1967), who noted that in 1967 the bulk of the catches off Norway consisted of the 1962 year class. (In the previous report (Polonsky and Golubjatnikova, 1970) it was erroneously stated :"Our data do not coincide with the material of Draganik"... The authors express their apology to Mr Draganik for this inaccuracy.)

In 1969-1970 the strong 1966 and 1967 year classes predominated in the catches. The bulk of the catches consisted of saithe of 39-70 cm long and 3 to 6 and even 7 years old (Tables 4 and 5).

No particular differences were observed in the size composition between the catches by commercial trawls and those by trawls with a fine-meshed cover except for 1967. Some variations in the size composition of the catches in 1967 are explained by the great abundance of yearlings of a strong year class. Our data coincide with the material of Reinsch (1969), who noted a high abundance of saithe yearlings in the North Sea in August-November 1967.

As stated earlier (Polonsky and Golubjatnikova, 1970) an increase in the mean size and mean age of saithe occurred in the North Sea up to 1968 inclusive. In 1968 - 1970, the introduction of the young 1966 and 1967 year classes into the fishery resulted in some decrease in the mean size and mean age.
