

European eel (*Anguilla anguilla*) throughout its natural range

ICES advice on fishing opportunities

ICES advises that when the precautionary approach is applied for European eel, all anthropogenic impacts (e.g. caused by recreational and commercial fishing on all life stages, hydropower, pumping stations, and pollution) that decrease production and escapement of silver eels should be reduced to, or kept as close as possible to, zero in 2021.

Stock development over time

The status of European eel remains critical.

Indices of both glass and yellow eel recruitment strongly declined from 1980 to 2011. The latest glass eel recruitment in the “North Sea” index area, compared to that in 1960–1979, was 0.5% in 2020 (provisional) and 1.4% in 2019 (final). In the “Elsewhere Europe” index series it was 6.5% in 2020 (provisional) and 5.6% in 2019 (final), based on available dataserries. For the yellow eel dataserries, recruitment for 2019 was 17% (final) of the 1960–1979 level; the 2020 data collection for yellow eel is ongoing. Statistical analyses of the time-series from 1980 to 2020 show that glass eel recruitment remains at a very low level’.

Figure 1 European eel. **Left panel:** Indices, geometric mean of estimated (generalized linear model; GLM) glass eel recruitment for the continental “North Sea” and “Elsewhere Europe” series. The GLM was fitted to 52 time-series, comprising either pure glass eel or a mixture of glass + yellow eels (24 “North Sea” and 28 “Elsewhere Europe”). The predictions were then scaled to the 1960–1979 average $\bar{p}_{1960-1979}$. The “North Sea” series are from Norway, Sweden, Germany, Denmark, the Netherlands, and Belgium. The “Elsewhere” series are from UK, Ireland, France, Spain, Portugal, and Italy. In the Baltic area, recruitment occurs at the yellow eel stage only, and series are thus not included in the glass eel recruitment index. **Right panel:** Estimated (GLM) yellow eel recruitment trends for Europe. The GLM was fitted to 16 yellow eel time-series and scaled to the 1960–1979 average $\bar{p}_{1960-1979}$. The series are from Denmark, Germany, Ireland, Sweden, and the UK.

Stock and exploitation status

ICES cannot assess the exploitation status relative to the maximum sustainable yield (MSY) and precautionary approach (PA) reference points, because the reference points are undefined. While stock-size reference points are also undefined, it is considered likely that the stock size is well below potential biological reference points.

Table 1 European eel. State of the stock and the fishery relative to reference points.

	Fishing pressure				Stock size					
		2018	2019	2020		2018	2019	2020		
Maximum sustainable yield	F_{MSY}	?	?	?	Unknown	MSY	⊗	⊗	⊗	Below potential reference points
Precautionary approach	$F_{pa}F_{lim}$?	?	?	Unknown	$B_{pa}B_{lim}$	⊗	⊗	⊗	Below potential reference points
Management plan	F_{MGT}	—	—	—	Not applicable	B_{MGT}	—	—	—	Not applicable
Qualitative evaluation	-	?	?	?	Unknown	-	?	?	?	Highly impaired recruitment

Catch scenarios

ICES does not have the information needed to provide a reliable estimate of the total catches of eel. Furthermore, the understanding of the stock dynamics is not sufficient to determine/estimate the level of impact that fisheries or non-fisheries anthropogenic factors (at the glass, yellow, or silver eel stage) have on the reproductive capacity of the stock.

Basis of the advice

Table 2 European eel. The basis of the advice.

Advice basis	Precautionary approach.
Management plan	<p>A management framework for eel within the EU was established in 2007 by Council Regulation (EC) No. 1100/2007 (EU, 2007; also referred to as the “Eel regulation”), but no internationally coordinated management plan exists for the entire stock area, which extends beyond the EU.</p> <p>The objective of the EU regulation is the protection, recovery, and sustainable use of the stock. To achieve that objective, EU Member States have developed Eel Management Plans (EMPs) for their river basin districts. These are designed to reduce anthropogenic mortalities, permitting with high probability the escapement to the sea of at least 40% of the silver eel biomass. This is relative to the best estimate of escapement that would have existed if no anthropogenic influences had impacted the stock.</p> <p>Council Regulation (EC) No. 1100/2007 (EU, 2007), establishing measures for the recovery of the stock of European eel, has not been evaluated by ICES for its conformity with the precautionary approach and, for this reason, has not been used as the basis for the advice. ICES work is progressing in this area.</p> <p>Since 2018, a consecutive three-month closure for eel commercial fishing has been in place at the EU level under the Fishing Opportunities Regulation for eels above 12 cm in European Union waters of ICES area, including in the Baltic Sea (EU, 2018). These measures have been modified and rolled over to 2020 (EU, 2019, 2020a).</p> <p>The General Fisheries Commission for the Mediterranean (GFCM) adopted Recommendation GFCM/42/2018/1 (GFCM, 2018), establishing management measures for European eel (<i>Anguilla anguilla</i>) in the Mediterranean Sea, comprising a consecutive three-month closure period. Work is ongoing towards the development of an adaptive regional management plan for eel in the Mediterranean Region under the auspices of GFCM.</p>

Quality of the assessment

The advice is based on two glass eel recruitment indices and a yellow eel recruitment index, each comprised of multiple time-series. The indices are based on data from fisheries and scientific surveys, forming the longest and most reliable time-series that constitute an index of abundance. The quality of the underlying recruitment data and the number of time-series reported yearly is variable. The current advice is based on the fact that the indices used by ICES are well below the 1960–1979 levels. The decline in yellow eel recruitment becomes more pronounced when data from the 1950s are used rather

than the currently used baseline. However, because so few robust pre-1960s time-series are available, the baseline was set to 1960–1979 as in previous advice.

An eel data call, issued for the first time in 2017, substantially improved the coverage and completeness of the data being reported to ICES. Subsequent annual calls were issued, including every third year the national stock indicators and associated data as reported to the EU in the progress reports. The most recent call was issued in 2020 (ICES, 2020a). Data on eel, fisheries, and other anthropogenic impacts across the whole stock, however, remain incomplete. There is no international legislative requirement to collect and provide data that cover the entire stock area.

In 2018, nine of 95 eel management plans did not report all biomass indicators, and 17 did not report all mortality indicators (ICES, 2018). Differences persist in the approaches used to calculate reported stock indicators, which might not necessarily cover the entire distribution area of the species. A complete reporting of standardized and quality-checked indicators, covering the entire distribution area of European eel, is required.

Issues relevant for the advice

Many fishery-based time-series are utilized to assess temporal trends in recruitment and escapement. Changes to these time-series (e.g. through new fishery regulations or changes to habitat) may introduce biases in the time-series and compromise their use in the analyses. Sensitivity analyses showed that the current assessment was not sensitive to changes in fishery-based time-series; yet, losing these time-series would increase the noise in the outcome (i.e. standard error around the trend increases). This means that the implementation of new fishery-independent time-series should be encouraged, especially since all time-series need to run for ten years before they can be incorporated into the recruitment index.

Of the 68 datasets currently included in the recruitment trend used in the advice for the 2020 data call, 12 (i.e. 17%) recorded significant reductions to the sampling efforts directly attributed to COVID-19 impacts. The bulk of these reductions occurred across the western edge of Europe, coinciding with the spread of COVID-19 across the continent during spring, affecting six sites from the North Sea (NS series), four from the Elsewhere Europe (EE), and two for yellow eel recruitment. In the total dataset of 95 series (the database also includes series that are either too short or too biased to be included in the analysis), 17 of these series were affected. Note that of those index series used to assess recruitment trends, only one, normally reported at the time of WGEEL, was absent (SeEAG on the Severn UK).

Total landings and effort data are incomplete. In addition, a great heterogeneity is present among the time-series of landings owing to inconsistencies in reporting by, and between, countries. However, there has been a considerable improvement in both data consistency and area coverage since the introduction of standardized eel data calls in 2017. Changes in eel management practices have also affected commercial and non-commercial/recreational fisheries and the reporting of these fisheries.

The European eel has been listed in the IUCN Red List as Critically Endangered since 2008.

The European eel (*Anguilla anguilla*) has been listed in CITES Appendix II and in the EU implementation of CITES rules (Annex B to Council Regulation (EC) No 338/97; EU, 1996) since 13 March 2009. Since 2010, import and export of eel from the EU has been prohibited. Some non-EU range states allow export of European eel, mostly to the Far East.

The assessment and management of the fisheries and non-fisheries mortality factors are carried out by national and regional authorities. Fisheries take place on all available continental life stages throughout the distribution area, although fishing pressure varies from area to area, from almost nil to heavy overexploitation. Illegal, unreported, and unregulated (IUU) fishing is known to occur. The non-fishing anthropogenic mortality factors can be grouped into those resulting from the following: (a) hydropower, pumping stations, and other water intakes; (b) habitat loss or degradation; (c) pollution, diseases, and parasites; and (d) other management actions that may affect levels of predation (e.g. conservation vs. control of predators). Climate change may have further effects, but these have not been quantified.

ICES has considered the quantification of the impacts of non-fishery factors (ICES, 2019a, 2020b). The current total potential loss of eel to all non-fishery anthropogenic mortalities (largely hydropower and pumps), from approximately half of the countries reporting to ICES, amounted to 1625 tonnes annually. This estimate would require further improvement

through better and more consistent data delivery from EU Member States. A quantitative assessment of the effects of habitat loss proved to be challenging through lack of appropriate data; this will be addressed in future data calls.

Environmental impacts in marine, transitional, and freshwaters all contribute to the anthropogenic stresses on eels, their mortality, and their reproductive success; these include, e.g. habitat alteration, barriers to eel passage, deterioration in water quality, and the presence of non-native species, diseases and parasites. The implementation of environmental legislation (e.g. the EU Water Framework [WFD] and the Marine Strategy Framework directives [MSFD]) that result in improvements to the continental environment may also have a positive effect on the reproductive potential of silver eel.

ICES notes that the restocking of eels, which is considered a management action in the EU regulation and in many eel management plans, is reliant on a glass eel fishery catch. Evidence shows that translocated and stocked eel can contribute to yellow and silver eel production in recipient waters, but information on the contribution to actual spawning is missing because of a general lack of knowledge of eel spawning. Internationally coordinated research is required to determine any net benefit of restocking on the overall population, including carrying capacity estimates of glass eel source estuaries, detailed mortality estimates at each step of the restocking process, and performance estimates of stocked vs. non-stocked eels.

Estimation of the prospective net benefit should be carried out prior to any restocking activity, such as increasing silver eel escapement by restocking to attain stock recovery. Restocking should take place only where survival in silver eel escapement is high, and it should not be used as an alternative to reducing anthropogenic mortality. Where eel are translocated and stocked, measures should be implemented to evaluate their fate and their contribution to silver eel escapement. Such measures should include regionally-coordinated mass marking of eels to distinguish stocked eels from natural recruits in future scientific surveys.

Recruitment at the 1960–1979 level is currently regarded as an unimpaired recruitment level.

Reference points

No defined reference points are used by ICES for this stock.

** There are no ICES catch estimates for the complete stock.

History of catch and landings

Landings data are not complete for the entire natural range of the European eel. However, Tables 5–8 present the landings reported to ICES, the European Inland Fisheries and Aquaculture Advisory Commission (EIFAAC), and GCFM. Landings are reported either through responses to the ICES data call (ICES, 2020a), in country reports (Annex 6 in ICES, 2020b), or integrated by ICES in 2017 (ICES, 2017), using data from previous reports. Not all countries have reported all their landings; hence, the values indicated here should be considered a minimum. Care should be taken with the interpretation of landings as indicators of the stock since the landings statistics now reflect the status of reduced fisheries activity as well as of stock levels.

Data deficiencies in reports on recreational fisheries (Tables 7–8) were described by ICES (2016). Though there has been evidence of improvements since then, the amount of landings in recreational fisheries remains largely unquantified. Estimates from countries, where they are available, show that landings in recreational fisheries can be of the same order of magnitude as in commercial fisheries (except for glass eels).

Information on fishing effort and the capacity of the fisheries is lacking, information which is necessary to fully interpret the changes to the landings data over the years. The gathering of such information is challenging because of the wide variety of fisheries and gear types (ICES, 2019a).

Few countries reported the level of misreporting and illegal fisheries to ICES, EIFAAC, and GFCM (i.e. the seizure of illegal nets as well as the illegal trade of glass eels from countries both inside and outside the EU). However, customs seizures indicate that the illegal export of glass eel could be substantial, potentially exceeding the legal market.

Summary of the assessment

Table 9 European eel. Recruitment indices: geometric means of estimated (GLM) recruitment for glass eel in the continental “North Sea” and “Elsewhere Europe”, and recruitment of yellow eel in Europe. The glass eel GLM (predicting recruitment as a function of area, year, and site) was fitted to 52 time-series, comprising either pure glass eel or a mixture of glass eels and yellow eels and scaled to the 1960–1979 geometric mean so that values correspond to the recruitment as a percentage of 1960–1979. The yellow eel GLM (predicting recruitment as a function of year and site) was fitted to 16 yellow eel time-series and scaled to the 1960–1979 geometric mean so that values correspond to the recruitment as a percentage of 1960–1979. These indices are updated on an annual basis and, as they are presented in relative terms, these updates may change the historical values. Confidence intervals (CI) = 95%.

Year	Elsewhere Europe index	North Sea index	Yellow eel Europe index	Elsewhere Europe index		North Sea index		Yellow eel index
